

Natural Language Scheduler (AI Calendar Automation)

1. Process Planing

This project automates the process of creating calendar events from natural language input. Normally, users must manually open a calendar application, select a date and time, and type event details. This process is repetitive and time-consuming. The proposed system allows users to simply type a message such as:

“Meeting with team tomorrow at 3pm”

The system will automatically interpret the message and create a structured calendar event without manual input.

2. Why this is useful

This automation improves productivity and reduces friction in daily scheduling. Users can quickly “brain-dump” their plans without worrying about formatting or navigating calendar interfaces.

It is especially useful because:

- It saves time by removing manual steps
- It allows natural communication instead of structured input
- It reduces the effort required to stay organized

Additionally, this system demonstrates how AI can be used to solve real-world inefficiencies in everyday tasks.

3. AI tools to be used

The project will use a no-code automation approach with the following tools:

- **Trigger/Input:** Telegram Bot
- **Automation Platform:** Make.com
- **AI Processing:** OpenAI API (GPT-4o)
- **Output:** Google Calendar API

The AI component is essential because it processes and understands natural language, converting unstructured text into structured data.

4. How the automation will work (Workflow)

The automation follows these steps:

1. The user sends a message (e.g., “Dentist appointment tomorrow at 2pm”).
2. The message is captured by Make.com through a trigger (Telegram or form).
3. The text is sent to the OpenAI API with a prompt to extract structured data (title, date, and time).
4. The AI converts the text into a structured JSON format.
5. Make.com maps the extracted data to the required fields.
6. Google Calendar automatically creates the event.

This process runs automatically after the initial trigger without manual intervention.

6. Role of AI in the automation

AI is a core part of this system. It enables the understanding of natural language expressions such as “tomorrow”, “next week”, or “3pm-ish”, which cannot be reliably handled using traditional rule-based programming. Without AI, the system would not be able to interpret flexible human input.

This project demonstrates a practical and meaningful use of AI-powered automation by transforming unstructured user input into actionable calendar events. It highlights both the usefulness of automation and the importance of AI in handling real-world language complexity.
